ABSTRACT

Purpose: Research involves the creation and implementation of new ideas by keeping the existing work as a foundation. The literature review done in this paper is to familiarise and to know about the domain of research to integrate the existing ideas with the new ones.

Methodology: The literature that is required for this study is chosen from multiple secondary sources such as journals, conference proceedings, and web resources. All the pieces of literature are carefully studied and summarised. This is further used to arrive at Research agendas and Research gaps.

Findings/Result: It has been observed and understood that Natural Language Processing (NLP) is a field involving analysis and processing of textual contents. It also requires Machine Learning Algorithms to support the processing. This combination has already been used in various domains, the important one being the health sector. EMR data is huge and NLP can successfully process and prioritize them in different dimensions. In that direction, the same concept and technology can be applied to Software Engineering also and Requirements can be prioritized.

Originality: This literature review study is carried out using secondary data which is collected through various online sources. The information thus gathered will be used in the future to build upon existing theory and framework or build a new methodology. It is also seen that any conclusion or decision is not biased or unidirectional. A sincere effort is made to identify a research topic to carry out the research.

Paper Type: Literature Review.

Keywords: Software Development, Software Requirement Prioritization, Natural Language Processing, Machine Learning, Open Source NLP tools,

1. INTRODUCTION:

Software Development is a multistep, comparatively lengthy process where every stage of the development process includes milestones and deliverables. Requirement Elicitation (RE) of Requirement Gathering is one such stage that is considered as the heart of Requirements Engineering as it is highly critical, error-prone, and communication-dependent. Requirements Engineering is considered as an important and prominent subset of conventional Software Engineering or Development process as it involves using many tools and techniques to process the requirements and also sometimes developing new tools and techniques for the purpose [1]. RE phase in Software Development Life Cycle is meant to collect Requirements. These requirements are then classified as functional, non-functional, and domain specific requirements. These specifications are made available through the Software Requirement Specification (SRS) document. Functional requirements specify the functionalities that are expected out of the system to be developed and non-functional requirements are the features that affect the functionalities [2]. RE results in a huge amount of data and requirements from clients and stakeholders which is beyond the capability of humans to handle them and queue them in an orderly manner for implementation and consideration. The requirements thus elicited and classified are bound...
to have lots of ambiguity. These ambiguities may be one among lexical ambiguity, semantic ambiguity, or pragmatic ambiguity. Though the reasons for having ambiguity in requirements are many, classification and prioritization are huge concerns [3]. Software Requirements Prioritization (SRP) comes into use at this stage of Requirements Engineering. SRP is required to specify the order in which the long list of requirements given by the client needs to be processed. Hence SRP deals with the order of processing requirements. SRP aids in a better way of scheduling requirements [4]. All requirements collected come under either of one of the categories as mentioned earlier. Further, Requirements can be classified as low priority, medium priority, and high priority based on which they can be prioritized. As different stakeholders will have various opinions regarding the list of requirements, it becomes invariably important to set up an order in which requirements need to be implemented. It is also necessary to prioritize requirements as one needs to keep track of cost, time, and resources too [5]. It is believed that more than 85% of the defects and bugs in software are because of incorrect requirements and also not considering the important requirements. Hence, SRP is an important step in the Software Development process which requires at most potential and knowledge [6]. Several SRP techniques have been formulated so far which take up the prioritization process in various dimensions. Every method has its own merits, demerits, and constraints. One single method is not suitable for all types of development processes. Some of them are suitable for large applications while some techniques work well when the requirements size is small. Accordingly, the prioritization techniques are classified [7]. Prioritizing Software Requirements are essential from a developer’s perspective also. There will be requirements that are interdependent and also some of them would be implemented parallelly. Hence an appropriate technique is necessary to prioritize Functional Requirements to make developers work easy [4]. Moreover, Prioritizing Software requirements is an important activity as it brings down the problems and issues associated with resources, manpower, budget, etc. Not only this, the Prioritization process helps in getting rid of unwanted requirements which otherwise would cost a lot for the development team. Requirements are gathered at the beginning of the software development process. These are then prioritized according to their relative importance to the market and the product itself, considering several factors that can influence prioritization decisions [8]. Hence, Requirements Prioritization is a process that is just a step after the classification of requirements. This process involves three steps – first one is to find out which of the requirements need to be included and which of them need to be ignored; the second step is to find out if there are any dependent requirements; and finally, the third step is to do a prioritization [9].

The following figure throws more light on Requirement Prioritization in the Requirements Elicitation process.

Fig. 1: Requirement Elicitation Process and the place of Requirement Prioritization

In this paper, a review of various Software Requirements Prioritization methods is done and also various avenues, possibilities, and technologies that can support the automatic prioritization process. The paper is organized as follows – the next section talks about the Research objective. This is followed by a literature survey done on the topic and related topics. A total of about ten papers are reviewed and their findings are recorded and presented. There is a separate review done on the role of NLP in Software Engineering followed by a review on the use of ML and AI in NLP. The next section provides an
overview of various open source tools in NLP that are available for the purpose. This is followed by a small write up on repositories that are publicly available and contain Requirement Documents. A tabular review of Research papers in the domain and related work is also presented. A total of 50 papers are reviewed. The next section gives a brief overview of present work and possible future work. Research Gaps are identified in the next section which is also analyzed. In the end, a SLOC analysis is done on the topic.

2. RESEARCH OBJECTIVE AND METHODOLOGY:

Requirement Prioritization is considered to be the most significant step in Requirement Engineering which again comes under the umbrella of the Requirement Analysis phase of SDLC. Many methods and methodologies have been devised to prioritize requirements to make this step fruitful and beneficial and helps in analyzing the requirements of clients in a better way. Automating Requirements Prioritization is something that is the need of the hour as manual prioritization might be time consuming and biased to some extent. Finding ways of using technology, especially Natural Language Processing to do the task is the prime objective of this study. The other objectives include:

- Exploring different Requirement Prioritization techniques available
- Finding the various tools that are available to do Requirement classification
- Deciding a suitable technology for automated Requirement prioritization
- When multiple technologies are available for the purpose, finding the more appropriate ones
- Finding the right method/algorithm(s) to achieve Requirement Prioritization

3. LITERATURE SURVEY:

Olaronke, I., et al (2018) [10] have examined different techniques for prioritizing needs by stating their strengths and weaknesses. In the research paper, they have analyzed and compared technologies such as binary search tree, AHP, AHP hierarchical structure, priority group/numerical analysis, bubble classification, MoSCoW, simple classification, and planning game. It is also concluded that the numerical value assignment and simple classification methods require less time in the prioritization process, and their scalability and reliability are also lower. It has also been said that the AHP process takes more time to prioritize requirements; it is reliable but not scalable. The research study made by them has also shown that when multiple stakeholders are involved, it is difficult to prioritize requirements using existing prioritization techniques due to the different perspectives of different stakeholders.

Perini, A., et al (2013) [11] describes a novel requirements prioritization method called Case-Based Ranking (CBRank). CBRank combines stakeholders' preferences with requirements ordering approximations which are computed through Machine Learning techniques. It follows a method called case based approach in which solutions to a problem are derived through previously solved similar problems. Hence in Requirements Prioritization, previously ranked prioritizations are taken and approximate ranks are calculated for the new set of requirements. An algorithm called the RankBoost algorithm is also considered here for Prioritizing requirements.

In their paper, Ejaz, K., et al [12] have proposed a simple yet novel model for Requirements Prioritization. According to them, the requirements are given by the clients to the Project Manager who in turn compiles them into optimal data. This data helps in determining the cost and benefits which can tell about the feasibility of implementation. This is done with the help of a high level algorithm called the Greedy algorithm and a low level algorithm. The authors further state that this can be developed into an intelligent system with the help of technical attributes.

Choudhary S., et al [13], in their work have discussed about email prioritization using Machine Learning algorithms. Naïve Baye’s Classifier is used here for the classification of emails. Here weights are assigned to certain words in emails. Then these weights are totaled up to prioritize emails based on weights. NLP is used to find important words and their corresponding meaning.

According to Singh, M., et al [14], verification and validation of radiology reports and their prioritization can be done by using a Naive Bayesian classifier. One hundred reports were used to train the model as high priority and low priority following which this model was used to evaluate three
hundred and fifty four reports. The model developed for this purpose using the Naïve Bayes classifier is also reported to have given an accuracy of 93.50%.

Amora, P. R. P., et al [15] in their research have combined sentiment analysis and prioritization of user comments and reviews. Tweets from social media by the customers are analyzed and classified to do a sentiment analysis. The tweets are then attended based on the priority so that the company will not lose any customers because of not attending to their dissatisfaction. Hence all comments and reviews are prioritized and actions are taken accordingly. To do this, the authors have used many Machine learning algorithms including a couple of deep learning algorithms such as LSTM and Bi-directional LSTM to achieve customer service prioritization.

In their paper, Muqeem, M., et al [16] propose a fuzzy based approach for Requirement prioritization. Here the requirements prioritization is done immediately after requirement elicitation. Here the attributes are taken as fuzzy variables. Later these variables are processed in an inference system and the ranking is given by the expected value of the fuzzy variable.

Sharma, N., et al [17] have discussed about the direction of research in Software Engineering and Natural Language Processing. They have given a detailed list of Software Engineering domains according to SEBOK (Software Engineering Body of Knowledge). Furthermore, two approaches of NLP namely the Classical approach and Empirical & Statistical approach are specified. The authors also describe the methods to generate research questions and produce Research products in Software Engineering and NLP.

Vibha G., et al [18] have evaluated various software requirements prioritization methods available considering multiple attributes and also tried to identify ways to decide the prioritization method most suitable for an application. To do this, the authors have used Fuzzy Multi-Criteria Decision Making Method (FMCMD) to choose an appropriate prioritization method. They have used an experimental study approach for finding out an appropriate method. Moreover, the newly proposed method is based upon the concept of fuzzy set theory.

In their paper Salado, A., et al [19] have spoken about deciding conflicting requirements. In this regard, the authors have proposed a new and elegant ARP model which provides information about priorities to use proper criteria on any decision at a given time. Also, this model helps handle priorities in a structured manner and aids in offering flexibility for specific needs of the project.

3.1 The role of NLP in Software Engineering:
Natural Language Processing (NLP) and Software Engineering – both domains have one feature in common that they are two important branches of Computer Science. The contributions of NLP and SE are enormous in their domains. Lots of research has been conducted to find various avenues of using NLP is SE. Lots of textual documents are generated during the Software Engineering process. Every phase of the Software Development Life Cycle has some artifacts generated at the end of every phase. A Software Requirement Specification Document is generated at the end of the Requirement Elicitation phase. Same way a Design document is generated at the end of the Design phase and various Test cases are documented during the testing phase. Hence, we see a wide range of opportunities to use NLP as the textual content is more [20].

In the Requirement Engineering phase itself, NLP can be applied in six different categories. They are Requirement classification, Requirement Prioritization, Requirement Ambiguity removal, Requirement Quality Assessment, and Analysis. The various techniques of NLP that can be applied for the above purpose are Tokenization, POS tagger, Text chunking, Parsing, VSM, TF-IDF [21]. UML class diagrams can be generated from the Requirements Specification document with the help of NLP and by applying other heuristic rules. NLP tools are devised which can map the knowledge extracted into UML class diagrams [22].

3.2 Use of Machine Learning and Artificial Intelligence in NLP:
NLP is a sub branch or field of Computer Science and computational linguistics which is driven by all the advances and researches in Machine Language (ML). NLP and ML are a part of Artificial
Intelligence (AI). AI is the umbrella under which NLP and ML exist. The following figure shows this relationship.

![Fig 2: Relationship between AI, ML, and NLP](image)

NLP is one of the text mining methods used for text analysis that implements a unique type of linguistic analysis that essentially makes the machine read and analyze [23]. ML and NLP together make a machine behave intelligently. Due to the advancement in NLP, the systems can accept information in a better way. AI helps systems to process the inputs and do better analysis and predictions by using Machine Learning algorithms and techniques [24].

### 3.3 Open Source NLP Tools:

In recent years, open source NLP tools have become more accessible. Unlike a decade ago when it was difficult to access tools for NLP, it is now the era of open source NLP tools. There are a huge number of tools available to do an automatic analysis of Natural language data. There are also separate tools developed for various languages too, while some of them can be used to analyze data of many languages. The following table summarises some of the open source NLP tools available.

**Table 2: List of various Open Source NLP tools**

<table>
<thead>
<tr>
<th>Name of the tool</th>

<td>--------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Apache OpenNLP [27]  | Apache OpenNLP library is a machine learning based toolkit that is used to process natural language text. | • POS  
• Named entities  
• Coreference  
• Sentiment  
• Quote attributions |
| MALLET [28]          | MALLET is a Java-based package for statistical natural language processing | • language detection  
• tokenization  
• sentence segmentation  
• POS tagging  
• named entity extraction  
• chunking  
• parsing  
• coreference resolution |
| GATE [29]            | GATE is an NLP tool capable of solving any type of text processing problem. | • Tokenization  
• Gazetteer  
• sentence splitter  
• part of speech tagger  
• named entities transducer  
• co reference tagger |
| spaCy [30]           | spaCy is an NLP tool mainly useful for advanced natural language processing written in Python and Cython. | • Tokenization  
• Lemmatization  
• Part-of-speech(POS) tagging  
• Entity recognition  
• Dependency parsing  
• Sentence recognition  
• Word-to-vector transformations  
• other cleaning and normalization text methods |
| Gensim [31]          | Gensim is used for unsupervised topic modeling and natural language processing, using modern statistical machine learning implemented in Python and Cython. | • Topic modeling |

Thus, it is seen that there are many tools available for analyzing Natural language. Some of these tools are written in Python, while tools like CoreNLP were originally written in Java. Unlike the scenario in the early 90s, many flavors of tools are available for Natural Language processing and analysis now. It is up to the users to decide the appropriate tool based on the need and necessities.

3.4 Repositories of SRS:
A Software Requirement Specification (SRS) document is the outcome of the Requirement Elicitation phase. This becomes the base for further developmental work that takes place. To carry out the automated Requirement Prioritization task, there must be standard SRS so that textual data from that can be analyzed and applied on algorithms being tested. The following are some of the publicly available repositories of SRS available.

4. DISCUSSION AND FUTURE WORK:

The review done shows that the existing Software Requirements Prioritization methods are not automated and they are done manually by using any of the methods that are mentioned. At the same time, it has been observed that Text Prioritization can be done with the help of Machine Learning Algorithms [89]. This has already been done in the Medical field to prioritize the treatment of patients.
based on their health records [90], [91]. Moreover, there are no specific methods for Requirements Prioritization during Software Development based on the type of application being developed [92]. Hence, there is a need to find out a way to develop an automated way of Prioritizing requirements in general and for every type of application being developed.

4.1 Proposed outline of Prioritizing requirements using NLP:
The following steps can be proposed in Prioritizing requirements:

a) All Software Requirement Specification documents will be stored in a repository.

b) All the specification documents will undergo pre-processing. This is done as a part of Data cleaning

c) The documents will be classified into different categories by using appropriate Machine Learning algorithms [93]

d) Weights can be applied to each document based on the keywords used for classification

e) All the classified documents can be rearranged based on the ML algorithms by finding the probability of each document [94]

f) Priority can be set to thus arranged documents

Fig. 3: Block diagram of steps proposed in Requirements prioritization method

5. RESEARCH GAP:
The Literature survey conducted with the identified keywords has shown various Requirement Prioritization methods. All these methods and techniques are suitable to prioritize requirements manually. There is no mention of automated prioritization of requirements. At the same time, instances of text prioritization using ML algorithms are present [95]. The following Research Gaps are identified-

Research Gap 1: Which of the available SRP methods can be automated? Out of so many Prioritization methods identified, which ones are suitable to be chosen for an automation process. It has to be evaluated based on efficiency and diligence.

Research Gap 2: Many categories and types of algorithms are available in NLP and Machine Learning [96]. Out of these which one can be applied for SRP? Different algorithms and methods are available in ML and NLP for classification and assigning priority. Which one/s among them will serve the purpose and needs to be worked on.

Research Gap 3: Are there different Prioritization techniques available for different types of applications to be built? Though there are no different ways of building a software application, it has to be seen if requirement prioritization methods can be different for various types of software applications.

Research Gap 4: Are there any other repositories for SRS other than the ones mentioned in this literature survey? There are very few public repositories that are available for SRS. Are there any means of finding out a few more for the purpose of research?
6. RESEARCH AGENDAS:
   i. What are the different techniques/algorithms available for prioritizing software requirements?
   ii. What are the characteristics and drawbacks of the existing software requirements prioritization techniques?
   iii. What are the technologies under study to automate the process of software requirements prioritization process?
   iv. What is the extent of research carried out in NLP and ML for text Prioritization?
   v. What are the techniques available/suitable for Software Requirements Prioritization using Natural Language Processing and Machine Learning?
   vi. What are the Open Source NLP tools available?
   vii. Which are the available repositories for Software Requirement Specification Documents?

7. ANALYSIS OF RESEARCH AGENDAS:

Different techniques are available for prioritizing requirements. Each one has its own merits and demerits. The purpose of using each of the techniques also varies. All the techniques available give a basic guideline or framework that can be applied to prioritize requirements. Hence a question arises as to how these techniques can be automated [97]. AI and ML algorithms can fit into some of the techniques and help in achieving prioritization tasks. A fair amount of research has already gone into text prioritization in the area of NLP and ML. This research has to be kept as a foundation or roadmap to further enhance it and apply it for Software Requirements. There are lots of open source tools available for working with Software Requirements. It has to be seen which among these will serve the purpose of Prioritization. Also, a suitable repository of Software Requirements Specification Documents has to be identified so that the effectiveness of the technique can be seen.

8. FINAL RESEARCH PROPOSAL IN CHOSEN TOPIC:

Automation of Requirement prioritization is something which the Software Industry would be looking for due to the ever increasing requirements and also the difficulties involved in prioritizing them [98]. There are very few pieces of evidence and research done on the automation process of prioritizing requirements. Lots of medical documents have been prioritized and subsequently used in the research thereof [99]. Similarly, the Software Requirements Specification document can be used as a source and the classified requirements can be prioritized by using NLP techniques backed by ML algorithms. On the first trial, this can be done for any type of applications. Hence, the closest topic could be-

**Implementation of Automated Software Requirements Prioritization by using NLP techniques**

9. SLOC ANALYSIS OF RESEARCH PROPOSAL:

SLOC analysis is done to analyze and assess Strengths, Limitations, Opportunities, and Challenges [100] [101]. The following is the result of the SLOC analysis conducted on the Research proposal.

**Table 5: SLOC analysis**

<table>
<thead>
<tr>

</tbody>
</table>

Opportunities

Challenges
Requirement Prioritization is an issue that is most sought after by the Software companies. This issue also opens up new avenues for Research.

Legal issues and corporate laws govern the data or Requirement Specification documents. Requirement Specification documents do not follow a uniform structure. Very few repositories of Requirement Specification documents are available.

10. CONCLUSION:
Tackling and handling issues in Software Development has always been challenging. Especially, the timely delivery of developed software to the stakeholders with all requirements fulfilled is commendable. Filling all requirements in an ordered way is the heart and soul of Software Development. Therefore, deciding the order in which the requirements need to be processed takes an upper hand in Software Engineering Research. There are many Requirement Prioritization techniques available. But all these techniques need to be carried out by the development team manually which is a cumbersome process and also bias prone. Hence, there is a need to automate the process of Requirement Prioritization. Literature review done in this regard shows that Natural Language Processing ably supported by Machine Learning if required can be used to achieve the task. Similar research has been studied in this regard. Appropriate Machine Learning Algorithms have to be analyzed for this purpose. A comparative study needs to be done in this regard to find out the best algorithm. Or if the need arises a new algorithm or method can be devised.
